

Problem Statement:

Develop a new model of health insurance charges prediction based input parameters of age, sex, bmi, childer and smoker.

Dataset details:

There are six columns and 60 rows in the dataset. The dataset has multiple input and one output. This multiple linear regression.

Independent fields: Age, Sex, BMI, Childern and Is Smoker

Dependent fields: Insurance Charge

Preprocessing Method:

There is a nominal data is available in the dataset, so we need to preprocess using one hot encoding algorithm

Model Evaluation

Support Vector Machine model evaluation:

No	Hyper Parameter	Linear (r value)	RBF (Non Linear)	Poly (r_value)	SigMod (r value)

Best Model:

Although the Support Vector Machine (SVM) model achieved the highest R^2 score, the best overall performance was observed with the Multiple Linear Regression model. The accuracy of this model is 0.759089037. This model, configured with a linear kernel and a correction value of 3000, provided the most reliable results based on the evaluation metrics.
